## Abstract

## 1 Introduction

### 1.1 Stern–Gerlach experiment

Suppose particles can be either black or white and we have some tool which can measure a color of particles. Additional, suppose, particles have additional property "hardness" - and we can measure whether particles are hard or soft. The properties are consistent - i.e. it doesn't matter how many times you measure it one after other, you get the same result. Also, hardness and color are independent - if you measure hardness, you get either white or black with same probability. The experiment itself is measuring color, then hardness, and then color again. Even though we input only white particles into hardness measuring tool, the output of second color measurement is either white or black with equal probability.

### Principles of quantum mechanics

1. Particle is described with normalized vector in complex space of physical states.

In our example, the space is 2D - black/white and hard/soft.

2. Given system in (normalized) state  $\vec{v}_1$ , probability that it will be in state  $\vec{v}_2$  is

$$P = |\vec{v}_2 \cdot \vec{v}_1|^2$$

So, in our example, suppose  $\hat{w}$  and  $\hat{b}$  are orthogonal basis of our space. Since we know that

$$\begin{cases} |\vec{w} \cdot \vec{s}|^2 = \frac{1}{2} \\ |\vec{b} \cdot \vec{s}|^2 = \frac{1}{2} \end{cases}$$

We know that angle with both axis of  $\vec{s}$  is  $\frac{\pi}{4}$ . We can choose any of 4 possibilities. Lets choose  $\hat{s} = \frac{\hat{w} + \hat{b}}{\sqrt{2}}$  and since  $\hat{h}$  is orthogonal,  $\hat{h} = \frac{\hat{w} - \hat{b}}{\sqrt{2}}$ .

3. Each measurement can be characterized with Hermitian operator, whose eigenvalues are outcomes of measurements and corresponding eigenvectors are states after the measurements.

Now we can predict the results of opposite experiment - if we measure hardness of white particle, it will be hard with probability  $\frac{1}{2}$ . Now the probability that resulting hard particle will be measured to be white, is also  $\frac{1}{2}$ .

In quantum mechanics we use bra ket notation: vector is denoted  $|b\rangle$  (conjugate transposed vector is denoted as  $\langle w|$ ):

$$|h\rangle = \frac{1}{\sqrt{2}} |b\rangle + \frac{1}{\sqrt{2}} |w\rangle$$

**Example** Suppose we have a particle

$$|\Psi\rangle = \frac{1}{\sqrt{3}} |w\rangle + \sqrt{\frac{2}{3}} |b\rangle$$

Then probability that it will be measured as white

$$P(w) = |\langle w|\Psi\rangle|^2 = \left| \frac{1}{\sqrt{3}} \langle w|w\rangle + \sqrt{\frac{2}{3}} \langle w|b\rangle \right|^2 = \frac{1}{3}$$

If measure hardness:

$$P(h) = |\langle h | \Psi \rangle|^2 = \left| \left( \frac{1}{\sqrt{2}} |b\rangle + \frac{1}{\sqrt{2}} |w\rangle \right) \left( \frac{1}{\sqrt{3}} |w\rangle + \sqrt{\frac{2}{3}} |b\rangle \right) \right|^2 = \left| \frac{1}{\sqrt{3}} + \frac{1}{\sqrt{6}} \right|^2 \approx 0.3$$

## 2 Linear algebra

**Linear operator** In quantum mechanics we write operators as multiplication of vectors. For example for

$$R = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$$

we write

$$R = -|w\rangle\langle b| + |b\rangle\langle w|$$

And then

$$R|\Psi\rangle = -|w\rangle\langle b|\Psi\rangle + |b\rangle\langle w|\Psi\rangle = -\langle b|\Psi\rangle|w\rangle + \langle w|\Psi\rangle|b\rangle$$

For example

$$R|s\rangle = |b\rangle\langle w|s\rangle - |w\rangle\langle b|s\rangle = |b\rangle\frac{1}{\sqrt{2}} + |w\rangle\frac{1}{\sqrt{2}} = |h\rangle$$

### Examples

•

$$W = |w\rangle\langle b| + |w\rangle\langle w|$$

•

$$T = |h\rangle\langle b| + |s\rangle\langle w|$$

•

$$Q = 2|w\rangle\langle w| + 3|b\rangle\langle b|$$

This is not unitary operator, since it doesn't conserve norm.

**Basis change** To change from basis to basis we just substitute the values of old basis in a new one:

$$T = |h\rangle\left(\frac{1}{\sqrt{2}}\langle h| - \frac{1}{\sqrt{2}}\langle s|\right) + |s\rangle\left(\frac{1}{\sqrt{2}}\langle h| + \frac{1}{\sqrt{2}}\langle s|\right) = \frac{1}{\sqrt{2}}|h\rangle\langle h| - \frac{1}{\sqrt{2}}|h\rangle\langle s| + \frac{1}{\sqrt{2}}|s\rangle\langle h| + \frac{1}{\sqrt{2}}|s\rangle\langle s|$$

**Hermitian operators** We want to build an operator  $C$  such that for state  $|\psi\rangle$  it will return us the average of  $\psi$ :

$$\langle\psi|C|\psi\rangle = \langle\psi\rangle$$

If we give a value of  $-1$  to white and value of  $1$  to black:

$$\langle\psi|C|\psi\rangle = -1 \cdot P(\psi = w) + 1 \cdot P(\psi = b) = -|\langle w|\psi\rangle|^2 + |\langle b|\psi\rangle|^2 = -\langle\psi|w\rangle\langle w|\psi\rangle + \langle\psi|b\rangle\langle b|\psi\rangle$$

Thus

$$C = -|w\rangle\langle w| + |b\rangle\langle b|$$

For example, for  $\psi = \frac{1}{\sqrt{3}}|w\rangle + \sqrt{\frac{2}{3}}|b\rangle$ :

$$\langle\psi|C|\psi\rangle = \langle\psi|(-|w\rangle\langle w| + |b\rangle\langle b|)\left(\frac{1}{\sqrt{3}}|w\rangle + \sqrt{\frac{2}{3}}|b\rangle\right) = \langle\psi|\left(-\frac{1}{\sqrt{3}}|w\rangle + \sqrt{\frac{2}{3}}|b\rangle\right) = \frac{1}{3}$$

**Additional example** Suppose we have two properties - color and temperature. Possible values are red, green, blue for color and hot, lukewarm, cold for temperature.

If we measure temperature of red or green particle we get lukewarm or hot with equal probability. If we measure temperature of blue particle we get cold surely.

How can we write  $|b\rangle$ ,  $|g\rangle$ ,  $|r\rangle$  in basis of  $|c\rangle$ ,  $|l\rangle$ ,  $|h\rangle$ ?

From first experiment

$$\begin{aligned} |r\rangle &= \frac{1}{\sqrt{2}} |l\rangle + \frac{1}{\sqrt{2}} |h\rangle \\ |g\rangle &= \frac{1}{\sqrt{2}} |l\rangle - \frac{1}{\sqrt{2}} |h\rangle \end{aligned}$$

Note that we need minus since else we'd get  $\langle g|r\rangle = 1$ . From last experiment

$$|b\rangle = |c\rangle$$

Lets denote  $h = 1$ ,  $l = 0$ ,  $c = -1$  and build temperature operator. It's characterized by

$$\begin{cases} T|h\rangle = |h\rangle \\ T|l\rangle = 0 \\ T|c\rangle = -|c\rangle \end{cases}$$

And thus an operator is

$$T = |h\rangle\langle h| - |c\rangle\langle c|$$

Now let's calculate temperature of state  $|g\rangle$ :

$$\langle g|T|g\rangle = \left( \frac{1}{\sqrt{2}} |l\rangle - \frac{1}{\sqrt{2}} |h\rangle \right) T \left( \frac{1}{\sqrt{2}} |l\rangle - \frac{1}{\sqrt{2}} |h\rangle \right) = \frac{1}{2} (|l\rangle - |h\rangle) T (|l\rangle - |h\rangle) = -\frac{1}{2} (|l\rangle - |h\rangle) |h\rangle = \frac{1}{2}$$

We can also calculate variance:

$$\sigma^2 = \langle g|T^2|g\rangle - (\langle g|T|g\rangle)^2$$

**Example** We have a particle can be at one of five points. So possible states are  $|1\rangle, |2\rangle, |3\rangle, |4\rangle, |5\rangle$ .

If we want to describe a particle on finite 1D interval, we'll divide it into  $N$  equal intervals of length  $a$ . We are interested in  $a \rightarrow 0$ , thus number of dimensions goes to infinity.

**double slit experiment**

## 3 Tons of linear algebra

...

### 3.1 Fourier transform operator

Define space with basis  $|x\rangle$  such that  $\langle x|f\rangle = f(x)$  and  $\langle x|x'\rangle = \delta(x - x')$  Define identity operator

$$I = \int |x\rangle\langle x| dx$$

Define also operator  $K$  such that

$$\langle x|K|f\rangle = -i \frac{\partial f}{\partial x}$$

$K$  is Hermitian if  $f \cdot g|_a^b = 0$  for any  $f, g$ .

It's eigenvalues  $k$  are such that

$$\langle x|k\rangle = \frac{1}{\sqrt{2\pi}} e^{ikx}$$

Also for  $f$

$$|f\rangle = \int f(x) |x\rangle dx = \int \hat{f}(k) |k\rangle dk$$

when

$$\langle k|f\rangle = \hat{f}(k)$$

Define operator  $X$  such that  $X|x\rangle = x|x\rangle$ . Obviously,  $X$  is Hermitian.

$$\langle x|X|f\rangle = (\langle f|X^\dagger|x\rangle)^* = (\langle f|X|x\rangle)^* = (x\langle f|x\rangle)^* = x^* \langle x|f\rangle = xf(x)$$

Lets calculate  $[X, K]$ :

$$\langle x|XK|f\rangle = \langle x|XIK|f\rangle = \int \langle x|X|x'\rangle \langle x'|K|f\rangle dx' = \int x'\delta(x-x')\left(-i\frac{\partial f}{\partial x'}\right) dx' = -ix\frac{\partial f}{\partial x}$$

Now

$$\langle x|KX|f\rangle = \int \langle x|K|x'\rangle \langle x'|X|f\rangle dx' = \int -i\delta(x-x')\frac{\partial}{\partial x'}(x'f(x)) dx' = -i\frac{\partial}{\partial x}(xf(x)) = -if(x) - ix\frac{\partial f}{\partial x}$$

Thus

$$\langle x|[X, K]|f\rangle = -ix\frac{\partial f}{\partial x} - \left(-if(x) - ix\frac{\partial f}{\partial x}\right) = if(x) = i\langle x|I|f\rangle$$

i.e.

$$[X, K] = iI$$

We suppose that our space is complete (i.e. each Cauchy sequence converges). Complete inner product space is called Hilbert space.

## 4 Quantum mechanics principles

1. Physical state is described by vector  $|\psi\rangle$  in Hilbert space
2. Given state  $|\psi\rangle$ , probability to measure it in state  $\varphi$  is

$$P = \frac{|\langle\varphi|\psi\rangle|^2}{\langle\varphi|\varphi\rangle\langle\psi|\psi\rangle}$$

3. Measurable quantities are described by Hermitian operator  $\Omega$ :
  - (a) Result of measurement is one of eigenvalues of  $\Omega$
  - (b) A state corresponding to measurement of value  $\omega$  is  $|\omega\rangle$ .
  - (c) After measurements, the state will be corresponding eigenvector
4. Given state  $\psi$  at  $t = 0$ , a state at time  $t$  is given by following PDE:

$$i\hbar\frac{\partial}{\partial t}|\psi\rangle = H|\psi\rangle$$

which is called Schrödinger equation

**Position and momentum operators** Position operator is  $X$  and momentum operator  $P = \hbar K$ .

### Consequences of principles

1. Particle on line is described with vector in infinite-dimensional space.
2. If  $|\psi\rangle$  and  $|\varphi\rangle$  are physical states,  $|\varphi\rangle + |\psi\rangle$  is physical state too.
3. It's impossible to predict results of measurements, only probability of results.
4. Norm of the vector is not important, since we always can normalize them.
5. Results of measurements of  $\Omega$  are only  $\omega_i$ .
6. If  $|\psi\rangle = |\omega\rangle$ , such that  $\Omega|\omega\rangle = \omega|\omega\rangle$  then measurement of  $\Omega$  will always give  $\omega$ .

7. Classical physical quantity which depends on  $x$  and  $p$ , its quantum analogue is same function of operators  $X$  and  $P$ :

$$\Omega(x, p) \Rightarrow \Omega(X, P)$$

The order is important, since  $[X, P] \neq 0$ . Some operators are defined only in quantum case, e.g.  $\Omega = [X, P]$ . Thus the right way to proceed is to define quantum quantities and then to check what happens in classical limit.

8. If there is degeneracy, i.e., some eigenvalue of the operator has multiple eigenvectors, the probability is a sum of probabilities:

$$P = |\langle \omega, 1 | \psi \rangle|^2 + |\langle \omega, 2 | \psi \rangle|^2$$

**Expectation and variance of measurement** Expectation of measurement can be calculated as

$$\langle \psi | \Omega | \varphi \rangle = \sum_i \omega_i P_\psi(\omega_i)$$

and variance

$$(\Delta\Omega)^2 = \langle \psi | (\Omega - \langle \psi | \Omega | \psi \rangle)^2 | \psi \rangle = \langle \psi | \Omega^2 - (\langle \psi | \Omega | \psi \rangle)^2 | \psi \rangle$$

## 4.1 Schrödinger equation

**Examples of Hamiltonian** For free particle

$$H = \frac{P^2}{2m}$$

For harmonic oscillator

$$H = \frac{P^2}{2m} + \frac{1}{2}\omega^2 X^2$$

Suppose Hamiltonian is independent on time. We want to diagonalize Hamiltonian.

**Diagonal Hamiltonian** If Hamiltonian is diagonal, we get very simple system of DEs:

$$\frac{dv_i}{dt} = m_i v_i$$

To diagonalize Hamiltonian we want to solve eigenvalue problem which is called time-independent Schrödinger equation:

$$H |E_i\rangle = E_i |E_i\rangle$$

As soon we have the solution we can rewrite  $H$  in eigenbasis:

$$H = \sum_i E_i |E_i\rangle\langle E_i|$$

Substituting

$$\begin{aligned} i\hbar \frac{\partial}{\partial t} |\psi\rangle &= \sum_k E_k |E_k\rangle \langle E_k | \psi \rangle \\ i\hbar \frac{\partial}{\partial t} \langle E_j | \psi \rangle &= -\frac{i}{\hbar} \sum_k E_k \langle E_j | E_k \rangle \langle E_k | \psi \rangle \\ \frac{\partial}{\partial t} \langle E_j | \psi \rangle &= -\frac{i}{\hbar} E_j \langle E_j | \psi \rangle \end{aligned}$$

This is equation which we can solve

$$\langle E_j | \psi \rangle = c_j e^{-\frac{iE_j}{\hbar}t}$$

We can rewrite  $\psi$  as

$$|\psi\rangle = \sum_k |E_k\rangle \langle E_k | \psi \rangle = \sum_k c_k e^{-\frac{iE_k}{\hbar}t} |E_k\rangle$$

we can find  $c_k$  from initial conditions

$$c_k = \langle E_k | \psi(0) \rangle$$

Note that if  $|\psi(0)\rangle = |E_j\rangle$ , then

$$|\psi(t)\rangle = e^{-\frac{iE_j}{\hbar}t} |E_j\rangle$$

What is probability to be in state  $|E_k\rangle$  at time  $t$ ?

$$P(|\psi(t)\rangle = |E_k\rangle) = |\langle E_k | \psi(t) \rangle|^2 = \left| e^{-\frac{iE_j}{\hbar}t} \langle E_k | E_j \rangle \right|^2 = \delta_{kj}$$

Thus eigenstates of Hamiltonian are called stationary states.

**Example** Suppose we have

$$\begin{cases} H|b\rangle = 0|b\rangle \\ H|w\rangle = E_\omega|w\rangle \end{cases}$$

Suppose that  $|\psi(0)\rangle = |h\rangle = \frac{1}{\sqrt{2}}|b\rangle + \frac{1}{\sqrt{2}}|w\rangle$ . What is probability to measure  $|h\rangle$  at time  $t$ ? We know the solution of Schrödinger equation is

$$|\psi\rangle = c_b e^{-\frac{i \cdot 0}{\hbar} t} |b\rangle + c_w e^{-\frac{i \cdot E_\omega}{\hbar} t} |w\rangle$$

From initial conditions  $c_b = c_w = \frac{1}{\sqrt{2}}$ :

$$|\psi\rangle = \frac{1}{\sqrt{2}}|b\rangle + \frac{1}{\sqrt{2}}e^{-\frac{i \cdot E_\omega}{\hbar} t} |w\rangle$$

Then

$$P(|\psi(t)\rangle = |h\rangle) = \left| \left( \frac{1}{\sqrt{2}}|b\rangle + \frac{1}{\sqrt{2}}e^{-\frac{i \cdot E_\omega}{\hbar} t} \langle w| \right) \left( \frac{1}{\sqrt{2}}\langle b| + \frac{1}{\sqrt{2}}\langle w| \right) \right|^2 = \left| \frac{1}{2} + \frac{1}{2}e^{-\frac{i \cdot E_\omega}{\hbar} t} \right|^2 = \frac{1}{2} \left( 1 + \cos\left(\frac{E_\omega t}{\hbar}\right) \right)$$

### Free particle in 1D

$$H = \frac{P^2}{2m}$$

In classical system  $X = \frac{P}{m}t$  and  $P = \text{const.}$

We want to find eigenvalues of

$$\frac{P^2}{2m}|E\rangle = E|E\rangle$$

In location representation:

$$\langle x|\frac{P^2}{2m}|E\rangle = E\langle x|E\rangle$$

In addition, from definition of  $P$ ,

$$\langle x|P|f\rangle = -i\hbar \frac{\partial}{\partial x} f(x)$$

Denote  $\psi_E(x) = \langle x|E\rangle$ . We get

$$\frac{1}{2m} \left( -i\hbar \frac{\partial}{\partial x} \right)^2 \psi_E(x) = E\psi_E(x)$$

We get

$$\frac{\partial^2}{\partial x^2} \psi_E(x) = -\frac{2mE}{\hbar^2} \psi_E(x)$$

For  $E > 0$  we get

$$\psi_{E,\pm}(x) = c_\pm e^{\pm \frac{i\sqrt{2mE}}{\hbar} x}$$

If  $E < 0$

$$\psi_{E,\pm}(x) = c_\pm e^{\pm \frac{\sqrt{2mE}}{\hbar} x}$$

those states are not physical, since they diverge in infinity.

**Algebraic solution** We search for

$$P|p\rangle = p|p\rangle$$

Since  $P = \hbar K$  and we know eigenstates of  $k$ :

$$K|k\rangle = k|k\rangle$$

Thus

$$|p\rangle = C|k\rangle$$

From

$$\langle p|p'\rangle = \delta(p - p')$$

we can find  $C$  and get

$$|p\rangle = \frac{1}{\sqrt{\hbar}}|k\rangle$$

Now

$$\frac{P^2}{2m}|p\rangle = \frac{p^2}{2m}|p\rangle$$

Thus  $E = \frac{p^2}{2m}$  and eigenvalues are  $|p\rangle$ .

To check whether this is the same solution, we calculate

$$\langle x|p\rangle = \langle x|\frac{1}{\sqrt{\hbar}}|k\rangle = \frac{1}{\sqrt{\hbar}} \langle x|k\rangle = \frac{1}{\sqrt{\hbar}} \frac{1}{\sqrt{2\pi}} e^{ikx} = \frac{1}{\sqrt{2\pi\hbar}} e^{\frac{ipx}{\hbar}}$$

Now we can get the solution

$$|\psi(t)\rangle = \sum_k c_k e^{-\frac{iE_k}{\hbar}t} |E_k\rangle$$

In our case

$$\begin{aligned} |\psi(t)\rangle &= \int_{-\infty}^{\infty} dp c(p) e^{-\frac{i\frac{p^2}{2m}}{\hbar}t} |p\rangle \\ \langle x|\psi(t)\rangle &= \int_{-\infty}^{\infty} dp c(p) e^{-\frac{i\frac{p^2}{2m}}{\hbar}t} \langle x|p\rangle \\ \psi(x, t) &= \frac{1}{\sqrt{2\pi\hbar}} \int_{-\infty}^{\infty} dp c(p) e^{-\frac{i\frac{p^2}{2m}}{\hbar}t} e^{-\frac{ipx}{\hbar}} = \frac{1}{\sqrt{2\pi\hbar}} \int dp c(p) e^{i\frac{px - \omega(p)t}{\hbar}} \end{aligned}$$

where  $\omega(p) = \frac{p^2}{2m}$ .

We know that

$$\psi(x, 0) = \frac{1}{\sqrt{2\pi\hbar}} \int_{-\infty}^{\infty} dp c(p) e^{\frac{ipx}{\hbar}}$$

Applying inverse Fourier transform

$$c(p) = \frac{1}{\sqrt{2\pi\hbar}} \int_{-\infty}^{\infty} dx \psi(x, 0) e^{-\frac{ipx}{\hbar}}$$

So suppose  $|\psi(0, x)|^2$  is Gaussian with expectation 0 and standard deviation  $\frac{1}{\sqrt{2}}\delta$ :

$$\langle x|\psi(0)\rangle = \psi(x, 0) = \frac{e^{\frac{x^2}{2\Delta}}}{(\pi\Delta^2)^{\frac{1}{4}}}$$

The average position of particle is then

$$\langle \psi(0)|X|\psi(0)\rangle = \int_{-\infty}^{\infty} dx' \langle \psi(0)|x'\rangle \langle x'|x|\psi(0)\rangle = \int_{-\infty}^{\infty} dx' \psi(x', 0) \langle x'|\psi(0)\rangle = \int_{-\infty}^{\infty} dx' |\psi(x', 0)|^2 x' = 0$$

Now

$$\langle \psi(0)|\Delta X^2|\psi(0)\rangle = \frac{\Delta^2}{2}$$

where

$$\Delta X = X - \langle \psi(0)|X|\psi(0)\rangle$$

Now we want to calculate momentum:

$$\langle \psi(0)|P|\psi(0)\rangle = \int dx' \psi(x', 0)^* \langle x'|P|\psi(0)\rangle = \int dx' \psi(x', 0)^* \left( -i\hbar \frac{\partial}{\partial x'} \psi(x', 0) \right) = 0$$

and its variance

$$\langle \psi(0)|\Delta P^2|\psi(0)\rangle = \frac{\hbar^2}{2\Delta^2}$$

To find probability density of momentum of particle, we need to find  $|\langle p|\psi(0)\rangle|^2$ :

$$\langle p|\psi(0)\rangle = \int dx \langle p|x\rangle \langle x|\psi(0)\rangle = \int dx \frac{1}{\sqrt{2\pi\hbar}} e^{-ipx} \psi(x, 0)$$

If we choose

$$\begin{aligned} \psi(x, 0) &= \frac{e^{\frac{x^2}{2\Delta}}}{(\pi\Delta^2)^{\frac{1}{4}}} e^{-\frac{ipx}{\hbar}} \\ \langle x\rangle &= \langle \psi(0)|x|\psi(0)\rangle = 0 \end{aligned}$$

$$\langle \Delta x \rangle = \langle \psi(0) | \Delta x | \psi(0) \rangle = \frac{\Delta}{\sqrt{2}}$$

and

$$\begin{aligned}\langle P \rangle &= p_0 \\ \langle \Delta P \rangle &= \frac{\hbar}{\sqrt{2}\Delta}\end{aligned}$$

Now we want to find  $\psi(x, t)$ , for that we search for  $c$ :

$$c(p) = \frac{1}{\sqrt{2\pi\hbar}} \int_{-\infty}^{\infty} dx e^{-\frac{ipx}{\hbar}} \psi(x, 0) = \dots = \frac{1}{\sqrt{\hbar}} \frac{e^{-\frac{(p-p_0)^2 \Delta^2}{2\hbar^2}}}{\left(\frac{\pi}{\Delta^2}\right)^{\frac{1}{4}}}$$

Thus

$$\psi(x, t) = \frac{1}{\sqrt{2\pi\hbar}} \int_{-\infty}^{\infty} dp c(p) e^{i\left(px - \frac{p_0}{m}t\right)\frac{1}{\hbar}} = \frac{1}{\pi^{\frac{1}{4}} \left(\Delta + \frac{i\hbar t}{m\Delta}\right)^{\frac{1}{2}}} \exp\left[-\frac{\left(x - \frac{p_0}{m}t\right)^2}{2\Delta^2\left(1 + \frac{i\hbar t}{m\Delta^2}\right)}\right] e^{i\frac{p_0}{\hbar}\left(x - \frac{p_0}{m}t\right)}$$

And thus probability density

$$P(x, t) = |\psi(x, t)|^2 = \frac{1}{\sqrt{\pi\left(\Delta^2 + \frac{\hbar^2 t^2}{m^2 \Delta^2}\right)}} \exp\left[-\frac{\left(x - \frac{p_0}{m}t\right)^2}{\Delta^2 + \frac{\hbar^2 t^2}{m^2 \Delta^2}}\right]$$

Thus

$$\begin{aligned}\langle x \rangle &= \frac{p_0}{m}t \\ \langle p \rangle &= p_0 \\ \Delta x &= \frac{\Delta}{\sqrt{2}} \sqrt{1 + \frac{\hbar^2 t^2}{m^2 \Delta^4}} \\ \Delta p &= \frac{\hbar}{\sqrt{2}\Delta}\end{aligned}$$

For small  $t$ ,

$$\Delta x \approx \frac{\Delta}{\sqrt{2}} \left(1 + \frac{\hbar^2 t^2}{m^2 \Delta^4} + \mathcal{O}(t^4)\right)$$

For large  $t$

$$\Delta x \approx \frac{\hbar t}{\sqrt{2}m\Delta}$$

**Substitute numbers** Suppose  $m = 1g$  and  $\Delta = 10^{-13}cm$  - size of proton.

For large  $t$

$$\Delta x = 10^{-14} \frac{cm}{s} \cdot t$$

Thus a time we'll need to wait  $10^{13}$  seconds until uncertainty becomes an order of  $10^{-1}cm$ .

**Substitute numbers** For electron,  $m \approx 9 \cdot 10^{-28}$  with same  $\Delta$ . We get

$$\Delta x \approx 10^{13} \frac{cm}{s} \cdot t$$

## 4.2 Almost constant potential

**Constant potential** For  $V = V_0$  lets solve

$$\begin{aligned}H |E\rangle &= E |E\rangle \\ \langle x | \frac{p^2}{2m} + V_0 |E\rangle &= E \psi_E(x)\end{aligned}$$

, where  $\psi_E(x) = \langle x | E \rangle$ .

$$\left(-\frac{\hbar}{2m} \frac{\partial^2}{\partial x^2} + V_0\right) \psi_E(x) = E \psi_E(x)$$

$$-\frac{\hbar}{2m} \frac{\partial^2}{\partial x^2} \psi_E(x) = (E - V_0) \psi_E(x) = \tilde{E} \psi_E(x)$$

Thus we get same solution, just with  $\tilde{E}$  instead of  $E$ :

$$\psi_E(x) = c_{\pm} e^{\pm \frac{\sqrt{2m\tilde{E}}x}{\hbar}}$$

for  $\tilde{E} > 0$ .

### Step potential

$$V = \begin{cases} 0 & x < 0 \\ V_0 & x > 0 \end{cases}$$

$E < V_0$  For  $x < 0$  we get solution with 0 potential:

$$\psi_E(x) = c_+ e^{\frac{ipx}{\hbar}} + c_- e^{-\frac{ipx}{\hbar}}$$

For  $x > 0$ :

$$\psi_E(x) = c_+ e^{\frac{\sqrt{2m(V_0-E)}x}{\hbar}} + c_- e^{-\frac{\sqrt{2m(V_0-E)}x}{\hbar}}$$

Here, the solutions don't diverge, since  $x \in (0, \infty)$ , thus only  $c_+ = 0$ .

Denote  $\kappa = \sqrt{2m(V_0 - E)}$

$$\psi(x) = \begin{cases} A_+ e^{\frac{ipx}{\hbar}} + B_- e^{-\frac{ipx}{\hbar}} & x < 0 \\ C e^{\frac{\sqrt{2m(V_0-E)}x}{\hbar}} & x > 0 \end{cases}$$

Now we want  $\psi_E$  be twice differentiable:

$$\begin{cases} A + B = C \\ \frac{ip}{\hbar}(A - B) = \frac{\kappa}{\hbar}C \end{cases}$$

From that we can find  $A(C)$  and  $B(C)$ , and  $C$ , as usual can be find from  $\langle E|E' \rangle = \delta(E - E') \Rightarrow \int_{-\infty}^{\infty} |\psi_E(x)|^2 dx = 1$ .

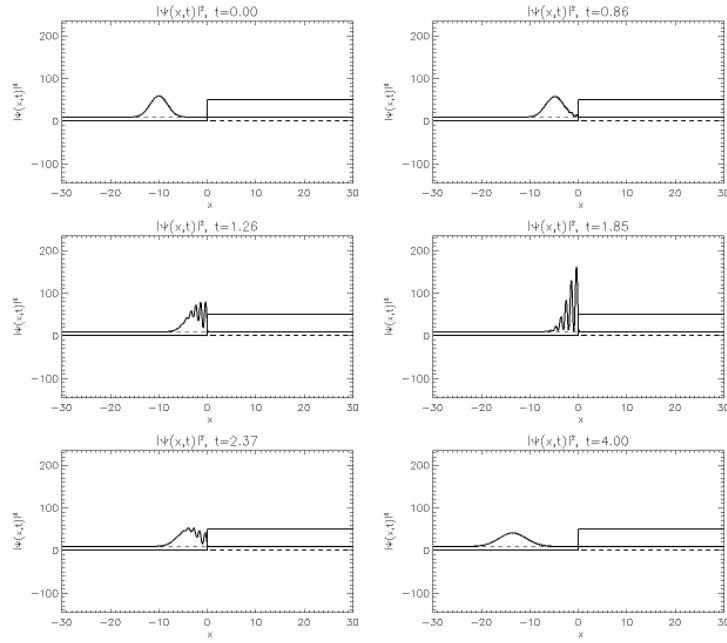

$E > V_0$

$$\Psi_E(x) = \begin{cases} A e^{-\frac{ipx}{\hbar}} + B e^{\frac{ipx}{\hbar}} & x < 0 \\ C e^{-\frac{i\tilde{p}x}{\hbar}} + D e^{\frac{i\tilde{p}x}{\hbar}} & x < 0 \end{cases}$$

From differentiability we get two bound conditions: we can get rid of two constants, say,  $A$  and  $B$ . Thus, for each eigenvalue there are two solutions: with  $C = 0$  and  $D = 0$ .

**Example** Suppose we have some particle in negative half of plane with momentum in positive direction. Since Hamiltonian is hermitian, we can rewrite  $\psi_0$  in eigenbasis.

$$\psi_0(x) = \sum_i c_i \psi_{E_i}(x)$$

#### 4.2.1 Potential well

$$V = \begin{cases} -V_0 & 0 < x < l \\ 0 & \text{otherwise} \end{cases}$$

Thus

$$\psi_E(x) = \begin{cases} Ae^{\frac{\kappa x}{\hbar}} & x < 0 \\ Ce^{\frac{ipx}{\hbar}} + De^{\frac{-ipx}{\hbar}} & 0 < x < L \\ Be^{\frac{\kappa x}{\hbar}} & x > L \end{cases}$$

From differentiability we can get rid of 2 constants in 0, and from 2 more in  $l$ . Thus in general, there is no solution, the only case is for specific values of  $E$ .

#### 4.2.2 Infinite potential well

What happens when  $V_0 \rightarrow \infty$ , in this case particle can't leave the well, i.e.  $\psi(x) = 0$ .

So we already have the solution:

$$\psi(x) = \begin{cases} Ae^{\frac{ipx}{\hbar}} + Be^{\frac{-ipx}{\hbar}} & 0 < x < L \\ 0 & \text{otherwise} \end{cases}$$

From  $\psi(0) = 0$  we acquire that

$$\psi(x) = C \sin\left(\frac{ipx}{\hbar}\right)$$

Since  $C \neq 0$  we get that  $p$  can acquire only particular values such that

$$\frac{pL}{\hbar} = n\pi$$

$$p = \frac{n\hbar\pi}{2}$$

Thus, since

$$H = \frac{p^2}{2m}$$

$$E_n = \frac{n^2\hbar^2\pi^2}{2mL^2}$$

and

$$\psi = C \sin\left(\frac{n\pi x}{L}\right)$$

### 4.2.3 General case

If we have piecewise constant potential:

For potential higher than energy we get decaying potential, and for each of wells we get oscillating solution.

## 4.3 Bound states

If we close to potential minimum, we can approximate it with Taylor series as

$$V \approx \frac{1}{2}m\omega^2 X^2$$

We will solve the Schrödinger equation for harmonic oscillator:

$$H |\psi_E\rangle = E |\psi_E\rangle$$

For

$$H = \frac{p^2}{2m} + \frac{1}{2}m\omega^2 X^2$$

In position representation we get

$$-\frac{\hbar^2}{2m}\psi_E + \frac{1}{2}m\omega^2 X^2\psi_E = E\psi_E$$

Lets perform variable substitution:

$$a = \sqrt{\frac{m\omega}{2\hbar}}X + i\frac{1}{\sqrt{2m\omega\hbar}}P$$

Since  $X, P$  are Hermitian

$$a^\dagger = \sqrt{\frac{m\omega}{2\hbar}}X + i\frac{1}{\sqrt{2m\omega\hbar}}P$$

$$a^\dagger a = \frac{mw}{2\hbar} X^2 + \frac{P^2}{2m\omega\hbar} + \frac{1}{2\hbar} i(XP - PX)$$

$$a^\dagger a = \frac{mw}{2\hbar} X^2 + \frac{P^2}{2m\omega\hbar} + \frac{1}{2\hbar} i[X, P]$$

$$[X, P] = \hbar[X, K] = i\hbar$$

Thus

$$H = \hbar\omega \left( a^\dagger a + \frac{1}{2} \right)$$

Denote  $N = a^\dagger a$  and  $N|n\rangle = n|n\rangle$ .

We can show that  $n \geq 0$  and

$$a|n\rangle = \begin{cases} |n-1\rangle & n \neq 0 \\ 0 & n = 0 \end{cases}$$

Which means that  $n$  has to be integer.
